

DYNAMIC STOPPING DISTANCE: REACTION LAG + KINETIC BRAKING

$$d_{\text{stop}}(t) = v(t) \cdot \Delta t_{\text{latency}} + v(t)^2 / (2 a_{\text{max}}) \leq d_{\text{clearance}}$$

1. SENSE-TO-ACTUATION REACTION DISTANCE

$$d_{\text{reaction}} = v_0 \cdot \Delta t_{\text{wall}}$$

- Vehicle travels at initial speed during computation lag
- Linear growth with latency: doubling latency doubles distance
- Example: at 1.5 m/s, $\Delta t=80$ ms $\Rightarrow d_{\text{reaction}} = 12.0$ cm

2. PHYSICAL KINETIC BRAKING DISTANCE

$$d_{\text{braking}} = v_0^2 / (2 \cdot a_{\text{max}})$$

- Dissipating kinetic energy $E_k = 1/2 m v^2$ against friction μ
- Quadratic growth with velocity: doubling speed quadruples distance
- Example: at 1.5 m/s, $a_{\text{max}}=3.0$ m/s² $\Rightarrow d_{\text{braking}} = 37.5$ cm

TOTAL DYNAMIC STOPPING CLEARANCE ENVELOPE

Total Stopping Distance: $d_{\text{stop}} = 49.5$ cm $\leq$ Clearance: 60.0 cm (Certified Safe)

If latency spikes to 200 ms (P99.9 tail), d_{reaction} becomes 30 cm $\Rightarrow d_{\text{stop}} = 67.5$ cm $>$ 60 cm $\Rightarrow$ COLLISION!
